From Reinforcement Learning to Beliefs

From Reinforcement Learning to Beliefs

What is Reinforcement Learning?

- ► Reinforcement learning is the study of how animals and artificial systems can learn to optimize their behavior in the face of rewards and punishments - Peter Dyan, Encyclopedia of Cognitive Science
- ▶ Not supervised learning the animal/agent is not provided with examples of optimal behaviour, it has to be discovered!
- ▶ Not unsupervised learning either we have more guidance than just observations

Links to other fields

- ▶ It subsumes most artificial intelligence problems
- ► Forms the basis of most modern "intelligent agent" frameworks
- ▶ Ideas drawn from a wide range of contexts, including psychology (e.g., Skinner's "Operant Conditioning"), philosophy, neuroscience, operations research, Cybernetics
- ▶ This will form the main framework our talk no need to understand everything
- Some of the things I am going to say might sound too introductory for someone familiar with RL

From Reinforcement Learning to Beliefs

From Reinforcement Learning to Beliefs

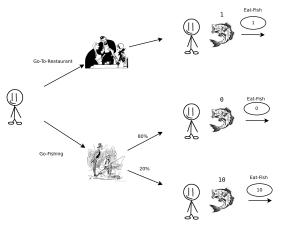

THE MARKOV DECISION PROCESS

- ightharpoonup The primary abstraction we are going to work with is the Markov Decision Process (MDP).
- ▶ MDPs capture the dynamics of a mini-world/universe/environment
- ▶ An MDP is defined as a tuple $\langle S, A, T, R, \gamma \rangle$ where:
 - $S, s \in S$ is a set of states
 - ▶ $A, a \in A$ is a set of actions
 - ▶ $R: S \times A$, R(s, a) is a function that maps state-actions to rewards
 - ▶ $T: S \times S \times A$, with T(s'|s,a) being the probability of an agent moving from state s to state s' after taking a
 - \triangleright γ is a discount factor the impact of time on rewards

Policy

- ► The MDP (the world) is populated by an agent (an actor)
- ► You can take actions (e.g., move around, move blocks)
- ▶ The type of actions you take under a state is called the *policy*
- $\blacktriangleright \pi: S \times A, \pi(s, a) = P(a|s),$ a probabilistic mapping between states and actions
- ▶ Finding an optimal policy is *mostly* what the RL problem is all about
- Goal is to maximise long term reward
- $J(\theta) = E_{\pi} \{ \sum_{t=0}^{\infty} R(s, a) \}$

FISHING TOON: PICTORIAL DEPICTION

EXPECTED REWARD

- ▶ Our toon has to choose between two different actions
- ► Go-To-Restaurant or Go-Fishing
- ightharpoonup We assume that toon is interested in maximising the expected sum of happiness/reward
- ▶ We can help the toon reason using the tree backwards

CORRECT ACTION

- ► Toon should go Go-Fishing
- ► Would you do the same?
- ▶ Would a pessimist toon do the same?
- \blacktriangleright We just went through the following equation:

$$Q^*(s,a) = R(s,a) + \gamma \sum_{s' \in S} T(s'|s,a) \max_{a' \in A} Q^*(s',a')$$

► Looks intimidating - but it's really simple

NO MODEL?

- ▶ The existance of an a-priori model is extremely unrealistic
- \blacktriangleright Three major classes of methods with dealing with this:
 - ► Model-free
 - $\blacktriangleright\,$ Learn policy directly by roaming around the world
 - \blacktriangleright Model based
 - \blacktriangleright Learn policy indirectly
 - ► Learn a model of the world
 - ► Learn a policy by "thinking hard"
 - ► Some combination of both (e.g., Dyna)
 - $\blacktriangleright\,$ Learn both a model and a policy from interactions
 - ► Improve the policy based on fictitious replays

12 / 38

From Reinforcement Learning to Beliefs From Reinforcement Learning to Beliefs FUNCTION APPROXIMATION Examples of model free methods ► States often have some kind of feature (e.g., distance, velocity, $\blacktriangleright \ \ \textbf{Q-learning:} \ \ Q(s,a) \leftarrow Q(s,a) + \eta \left[R(s,a) + \gamma \max_{a' \in A} Q(s',a') - Q(s,a) \right]$ ► SARSA(0): $Q(s, a) \leftarrow Q(s, a) + \prod_{i=1}^{L} R(s, a) + \gamma Q(s', a') - Q(s, a)$ ► SARSA(1)/MC: $Q(s, a) \leftarrow Q(s, a) + \prod_{i=1}^{L} V_{\tau} - Q(s, a)$ $V_{\tau} \leftarrow R(s, a) + \gamma R(s', a') + ... \gamma^{2} R(s'', a'') + \gamma^{\tau-1} R(s^{\tau}, a^{\tau})$ ► Too many states in any problem ▶ Learning based on these features ► Approximate Q-values, policies... ▶ η is a small learning rate, e.g., $\eta = 0.001$ ▶ Neural Networks, Linear Regressors, n-tuple networks etc... ► Global vs Local function approximators From Reinforcement Learning to Beliefs From Reinforcement Learning to Beliefs Some issues with model learning Why Learn a model? ► I can't find any good reasons to learn a model ► Errors Compound! ► Learning a model is most of the time MUCH harder than ► If you try to think far away, minor errors in the model add up learning to act based on states directly ► You end up with a completely broken future reward/transition ► Contradicts with our (my?) intuition \blacktriangleright We make inferences about the future all time + logical ► Unpublished reasoning, can't be that Q-values are enough! ► See here http://www.iclr.cc/lib/exe/fetch.php?media=iclr2015:silver-properties and the control of the c▶ Doing any large-scale learning requires tons of tricks (see iclr 2015.pdfDeep-Q learning by deep mind) ► Takes time to do ▶ Maybe we haven't found the right tricks for model-based stuff? From Reinforcement Learning to Beliefs From Reinforcement Learning to Beliefs Partial Observability **POMDPs** ► The usual MDP stuff: \triangleright S, $s \in S$ is a set of states ► It's unintuitive ▶ $A, a \in A$ is a set of actions • $R: S \times A, R(s, a)$ is a function that maps state-actions to ightharpoonup ... because the world is not fully observable rewards ► The Markov property does NOT hold! ▶ $T: S \times S \times A$, with T(s'|s, a) being the probability of an agent moving from state s to state s' after taking a▶ An observation is not enough to recover the state \triangleright γ is a discount factor - the impact of time on rewards ► Can you think of an example? ▶ Plus an observation model ► You cannot observe reality... ightharpoonup O is a finite set of observations, $o \in O$ • $\Omega: O \times S \to A$ is an observation function, with $\Omega(o|s',a)$ the

probability observation o was emitted when the agent landed in

state s after taking action a

THE BELIEF STATE	ON NETWORKS	ACTING ON BELIEFS FROM BELIEFS TO ATTENTION NETWORKS	
 ▶ Reality is unobservable ▶ We can keep track of observations and act on their historia. 	ries		
$h(s) = \{o_0o_n\} \tag{1}$ *Or we can find worthy stuff to believe in		 Now we can switch states, transitions, rewards with belief states, transitions, rewards We can try learning Q(b(s), a), since s cannot be observed We have no clue what b(s) is unless we have a model! But there is no way we can get this because we don't even have samples of T(s' s, a) 	
$b'(s') = (1/\eta)\Omega(o s', a) \sum_{s' \in S} T(s' s, a)b(s)$	(2)	► This is still possible (free energy learning schemes make this transparent)	
$\eta = \sum_{s' \in S} \Omega(o s', a) \sum_{s \in S} T(s' s, a)b(s)$	(3) (4)

SCALING UP		Attending over beliefs	
 ▶ We need to encode the belief model is some kind of distributed form ▶ Obviously, Recurrent Neural Networks (more later) ▶ Notice that the internal model has a relationship with the real world, but can have any form ▶ Game of Poker: ▶ External Model: The Game itself ▶ Internal Model: A probability distribution over possible opponent cards 		 Most of the things you believe in are unrelated to your current situation You must choose to believe in what is relevant Your beliefs about Poker are irrelevant when driving You need to focus only on relevant beliefs! But how? Let's call this attention mechanism T Possibly learning Q(T(b(s)), a) (attending over beliefs)?? Or Q(T(o₀oₙ), a) (attending over observations)?? 	
	21 / 38	22/38	
RESEARCH QUESTIONS	ON NETWORKS	PROM REINFORCEMENT LEARNING TO BELIEFS FROM BELIEFS TO ATTENTION NETWORKS NEURAL NETWORKS	
 ▶ What beliefs are worth having? ▶ Not all beliefs are created the same ▶ Some beliefs are counter-productive ▶ What's the impact of reward on broken beliefs? ▶ What beliefs are worth attending? ▶ How do we find out which beliefs to focus on? ▶ What does it mean to focus on different beliefs? ▶ How are beliefs transmitted? ▶ You can't possibly learn everything from experience ▶ Someone has to transmit beliefs directly to you 		 Non-linear global function approximators Can be learned iteratively through SGD Hard to get proofs of convergence for RL, work really well in practice Some issues: Catastrophic forgetting Global approximators A new sample will affect all knowledge stored Compare to updating a table (local approximator)

DISTANCE NETWORKS (MY STUFF)

- ► Encoding Paragraph
 - ▶ Embed Paragraph word by word
 - (Use RNN to get beliefs)
 - MaxPooling (get only most important features of each sentence)
- ► Embed Question
 - ► RNN (get only last state)
- ► Hop over data:
 - ► Subtract a the question vector from each sentence
 - \blacktriangleright Use a recurrent softmax mechanism to get the most relevant sentences

Word embeddings

- ▶ Each word in a sentence is given a numerical representation (i.e., "Bob" is given the number one)
- ▶ Each numerical representation is linked to a position within a matrix/vector, which points to weights
- ▶ Weights (after training) will provide us with a vectorial representation of words
- ► You tend to get nice properties like: King - Queen = Man - Woman

From Beliefs to Attention Networks

From Beliefs to Attention Networks

MaxPooling

From Reinforcement Learning to Beliefs

- ▶ Get only the most important features from the words of each sentence
- ► Pool on sentence level
 - ► For every sentence, find the each feature maximum (per word) and propagate only this

RNN encoder

- ► For the question sentence:
- \blacktriangleright Get the final vector representation as provided by an RNN
